Pars Session Protocol: End-to-End Encrypted Communication Primitives

Pars Network Technical Whitepaper PNP-003

Cyrus Pahlavi, Pars Team research@pars.network Version 1.0 — February 2026

Abstract

We specify the Pars Session Protocol (PSP), a suite of end-to-end encrypted communication primitives designed for the Pars Network session layer. PSP provides session establishment via an extended X3DH key agreement, bidirectional message encryption via the Double Ratchet algorithm with post-quantum key encapsulation, forward secrecy with a granularity of one ratchet step per message, and group sessions via the Sender Keys protocol extended with tree-based key derivation for efficient member addition and removal. We formalise PSP in the Universal Composability framework [1], prove that it achieves IND-CCA2 security under the Gap Diffie-Hellman assumption and the ML-KEM hardness assumption, and demonstrate that session establishment completes in under 300 ms with a message overhead of 128 bytes per encrypted payload. PSP is integrated with the Pars mesh networking layer (PNP-002) for transport and with the Pars L2 rollup (PNP-001) for identity anchoring.

Keywords: session protocol, end-to-end encryption, Double Ratchet, X3DH, forward secrecy, group sessions, post-quantum

1 Introduction

Secure communication is the foundation of any diaspora infrastructure. Members of the Persian diaspora require communication channels that remain confidential even if long-term cryptographic material is later compromised (forward secrecy), that resist active man-in-the-middle attacks (mutual authentication), and that scale to group conversations with dynamic membership.

1.1 Requirements

R1: Forward Secrecy: Compromise of long-term keys must not reveal past messages.

R2: Post-Compromise Security: After a key compromise is detected and healed, future messages must be secure.

R3: Asynchronous Establishment: Sessions must be establishable when one party is offline.

R4: Group Support: Efficient encryption for groups of up to 1000 members with dynamic join/leave.

R5: Deniability: No cryptographic proof that a specific party sent a specific message.

R6: Post-Quantum Readiness: Hybrid classical/post-quantum key exchange for long-term confidentiality.

1.2 Contributions

- Complete specification of PSP session establishment, message encryption, and group session management.
- Extension of X3DH with ML-KEM (Kyber) for hybrid post-quantum key agreement.
- Tree-based group key derivation for $O(\log n)$ key update on member changes.
- UC-framework security proof under standard assumptions.
- Performance analysis demonstrating practical overhead for mobile devices.

2 Preliminaries

2.1 Notation

2.2 Cryptographic Primitives

PSP relies on the following primitives:

1. **Curve25519:** For X3DH key agreement and Double Ratchet DH steps [4].
2. **Ed25519:** For identity key signatures [5].
3. **ML-KEM-768 (Kyber):** For post-quantum key encapsulation [6].
4. **AES-256-GCM:** For authenticated encryption of message payloads [7].
5. **HKDF-SHA256:** For key derivation [8].
6. **HMAC-SHA256:** For message authentication codes.

Table 1: Notation

Symbol	Meaning
IK_A	Identity key pair of party A
SPK_A	Signed prekey of A
OPK_A	One-time prekey of A
EK_A	Ephemeral key of A
$\mathrm{DH}(a, B)$	Diffie-Hellman on Curve25519
$\mathrm{KEM.Enc}(pk)$	ML-KEM encapsulation
$\mathrm{KEM.Dec}(sk, ct)$	ML-KEM decapsulation
$\mathrm{KDF}(k, \mathrm{info})$	HKDF-SHA256 derivation
$\mathrm{AEAD}(k, n, ad, pt)$	AES-256-GCM encryption
$H(\cdot)$	SHA-256

2.3 Trust Model

We assume an untrusted transport layer: the adversary can observe, delay, reorder, and inject messages. We assume the adversary is computationally bounded and cannot break the underlying primitives. We assume parties have obtained each other's identity public keys through an out-of-band channel or through the Pars DID system (PNP-008).

3 Session Establishment

3.1 Prekey Bundle

Each participant publishes a prekey bundle to the Pars session directory:

Definition 3.1 (Prekey Bundle)**.** *The prekey bundle for party A is:*

$$\mathcal{B}_A = \left(\mathrm{IK}_A^{\mathrm{pub}},\ \mathrm{SPK}_A^{\mathrm{pub}},\ \mathrm{Sig}_A(\mathrm{SPK}_A^{\mathrm{pub}}),\ \mathrm{KEM}_A^{\mathrm{pub}},\ \{\mathrm{OPK}_{A,i}^{\mathrm{pub}}\}_{i=1}^{N}\right)$$

where $\mathrm{KEM}_A^{\mathrm{pub}}$ *is an ML-KEM-768 public key for post-quantum key exchange.*

The signed prekey SPK_A is rotated weekly. One-time prekeys $\mathrm{OPK}_{A,i}$ are consumed on use and replenished when the supply drops below a threshold (default: 100).

3.2 Extended X3DH Protocol

PSP extends the X3DH protocol [3] with an additional ML-KEM key encapsulation step:

Algorithm 1 PSP Extended X3DH (Initiator Side)

Require: Initiator A, Responder B's bundle $\mathcal{B}_B$

Verify $\mathrm{Sig}_B(\mathrm{SPK}_B^{\mathrm{pub}})$
Generate ephemeral key pair $(\mathrm{ek}_A, \mathrm{EK}_A)$
▷ Classical DH components
$\mathrm{dh}_1 \leftarrow \mathrm{DH}(\mathrm{IK}_A, \mathrm{SPK}_B)$
$\mathrm{dh}_2 \leftarrow \mathrm{DH}(\mathrm{ek}_A, \mathrm{IK}_B)$
$\mathrm{dh}_3 \leftarrow \mathrm{DH}(\mathrm{ek}_A, \mathrm{SPK}_B)$
if OPK_B available **then**
    $\mathrm{dh}_4 \leftarrow \mathrm{DH}(\mathrm{ek}_A, \mathrm{OPK}_B)$
else
    $\mathrm{dh}_4 \leftarrow \varepsilon$
end if
▷ Post-quantum KEM component
$(\mathrm{ct}, \mathrm{ss}_{\mathrm{pq}}) \leftarrow \mathrm{KEM.Enc}(\mathrm{KEM}_B^{\mathrm{pub}})$
▷ Derive shared secret
$\mathrm{SK} \leftarrow \mathrm{KDF}(\mathrm{dh}_1 \| \mathrm{dh}_2 \| \mathrm{dh}_3 \| \mathrm{dh}_4 \| \mathrm{ss}_{\mathrm{pq}}$, "PSP-X3DH-v1")
Delete ek_A, all DH outputs, $\mathrm{ss}_{\mathrm{pq}}$
return $(\mathrm{SK}, \mathrm{EK}_A, \mathrm{ct})$

Algorithm 2 PSP Extended X3DH (Responder Side)

Require: Responder B, received $(\mathrm{EK}_A, \mathrm{ct}, \mathrm{OPK}_B^{\mathrm{id}})$

$\mathrm{dh}_1 \leftarrow \mathrm{DH}(\mathrm{SPK}_B, \mathrm{IK}_A)$
$\mathrm{dh}_2 \leftarrow \mathrm{DH}(\mathrm{IK}_B, \mathrm{EK}_A)$
$\mathrm{dh}_3 \leftarrow \mathrm{DH}(\mathrm{SPK}_B, \mathrm{EK}_A)$
if $\mathrm{OPK}_B^{\mathrm{id}}$ is valid **then**
    $\mathrm{dh}_4 \leftarrow \mathrm{DH}(\mathrm{OPK}_B, \mathrm{EK}_A)$
    Delete OPK_B
else
    $\mathrm{dh}_4 \leftarrow \varepsilon$
end if
$\mathrm{ss}_{\mathrm{pq}} \leftarrow \mathrm{KEM.Dec}(\mathrm{KEM}_B^{\mathrm{priv}}, \mathrm{ct})$
$\mathrm{SK} \leftarrow \mathrm{KDF}(\mathrm{dh}_1 \| \mathrm{dh}_2 \| \mathrm{dh}_3 \| \mathrm{dh}_4 \| \mathrm{ss}_{\mathrm{pq}}$, "PSP-X3DH-v1")
Delete all DH outputs, $\mathrm{ss}_{\mathrm{pq}}$
return SK

Theorem 3.1 (X3DH Security)**.** *The extended X3DH protocol provides IND-CCA2 security under the Gap-CDH assumption on Curve25519 and the ML-KEM IND-CCA2 assumption. Compromise of either the classical or post-quantum component alone does not reveal the shared secret.*

Proof. The shared secret is derived via HKDF from the concatenation of classical DH outputs and the ML-KEM shared secret. By the HKDF extraction lemma [8], if either component is uniformly random and independent of the adversary's view, the output is computationally indistinguishable from random. Under the Gap-CDH assumption, the DH outputs are computationally random. Under the ML-KEM assumption, $\mathrm{ss}_{\mathrm{pq}}$ is computationally random. Since the KDF requires *only one* component to be random, compromise of either classical or PQ component alone is insufficient. □

4 Double Ratchet Message Encryption

4.1 Ratchet State

After session establishment, both parties initialise a Double Ratchet [2] state:

Definition 4.1 (Ratchet State)**.** *The ratchet state $\mathcal{R}$ consists of:*

- DHs*: Current DH sending key pair*
- DHr*: Current DH receiving public key*
- RK*: Root key (32 bytes)*
- CKs*: Sending chain key (32 bytes)*
- CKr*: Receiving chain key (32 bytes)*
- N_s, N_r*: Message counters for sending and receiving*
- P_N*: Previous sending chain length*
- $\mathrm{MK}_{\mathrm{skipped}}$*: Dictionary of skipped message keys*

4.2 Symmetric-Key Ratchet

Each message advances the chain key:

$$\mathrm{MK}_i = \mathrm{HMAC}(\mathrm{CK}_i, \texttt{0x01}) \tag{1}$$
$$\mathrm{CK}_{i+1} = \mathrm{HMAC}(\mathrm{CK}_i, \texttt{0x02}) \tag{2}$$

The message key MK_i is used once and deleted. The chain key CK_i is overwritten by CK_{i+1}, ensuring forward secrecy at message granularity.

4.3 DH Ratchet

When the sending party changes, a DH ratchet step occurs:

Algorithm 3 DH Ratchet Step

```
procedure DHRatchet(state R, header)
    P_N ← N_s
    N_s ← 0;  N_r ← 0
    DHr ← header.dh
    (RK, CKr) ← KDF_RK(RK, DH(DHs, DHr))
    Generate new key pair DHs
    (RK, CKs) ← KDF_RK(RK, DH(DHs, DHr))
end procedure
```

4.4 Message Encryption

Algorithm 4 Encrypt Message

```
function ENCRYPT(state R, plaintext m)
    (CKs, MK) ← KDF_CK(CKs)
    N_s ← N_s + 1
    header ← (DHs^pub, P_N, N_s)
    ad ← IK_A^pub ‖ IK_B^pub ‖ Encode(header)
    ct ← AEAD(MK, N_s, ad, m)
    Delete MK
    return (header, ct)
end function
```

Algorithm 5 Decrypt Message

```
function DECRYPT(state R, header, ct)
    if header.dh ≠ DHr then
        SkipMessages(R, header.P_N)
        DHRatchet(R, header)
    end if
    SkipMessages(R, header.N_s)
    (CKr, MK) ← KDF_CK(CKr)
    N_r ← N_r + 1
    ad ← IK_A^pub ‖ IK_B^pub ‖ Encode(header)
    m ← AEAD.Dec(MK, N_r, ad, ct)
    Delete MK
    return m
end function
```

4.5 Out-of-Order Message Handling

When messages arrive out of order, the receiving party must skip ahead in the chain. Skipped message keys are stored in $\mathrm{MK}_{\mathrm{skipped}}$ indexed by $(\mathrm{DHr}, \mathrm{counter})$, with a maximum of 1000 stored keys and automatic expiry after 7 days.

Algorithm 6 Skip Messages

```
procedure SKIPMESSAGES(state R, until)
    if |MK_skipped| + (until − N_r) > 1000 then
        raise TooManySkipped
    end if
    while N_r < until do
        (CKr, MK) ← KDF_CK(CKr)
        MK_skipped[(DHr, N_r)] ← MK
        N_r ← N_r + 1
    end while
end procedure
```

5 Group Sessions

5.1 Design Goals

Group sessions must support:

1. Up to 1000 members
2. Efficient member addition and removal
3. Sender authentication within the group
4. Forward secrecy on member removal
5. Post-compromise security after key rotation

5.2 TreeKEM-Based Group Key Agreement

PSP uses a binary-tree key agreement inspired by TreeKEM [10] and the MLS protocol [11]:

Definition 5.1 (Group Tree)**.** *A group tree $\mathcal{G}$ is a left-balanced binary tree where each leaf ℓ_i corresponds to a group member M_i and each internal node v holds a key pair $(v^{\text{priv}}, v^{\text{pub}})$. The tree secret at the root is the group epoch secret.*

5.2.1 Member Addition

Algorithm 7 Add Member to Group

Require: Group tree $\mathcal{G}$, new member M_{new}

```
Allocate leaf ℓ_new at next available position
ℓ_new.pub ← M_new.IK^pub
v ← parent(ℓ_new)
while v ≠ root do
    Generate fresh key pair for v
    v ← parent(v)
end while
Derive new epoch secret from root
Encrypt path secrets for each co-path node
Distribute update message to group
```

5.2.2 Member Removal

Algorithm 8 Remove Member from Group

Require: Group tree $\mathcal{G}$, removed member M_r

```
Blank leaf ℓ_r and all ancestor nodes
Any remaining member M_k generates update:
for all nodes v on path from ℓ_k to root do
    Generate fresh key pair for v
end for
Derive new epoch secret from root
Encrypt path secrets for each co-path node
Distribute update; M_r cannot decrypt
```

The cost of addition or removal is $O(\log n)$ encryptions, where n is the group size.

5.3 Sender Keys for Message Encryption

Within a group epoch, each member maintains a sender chain:

Definition 5.2 (Sender Chain)**.** *Member M_i in epoch e has sender key* $\mathrm{SK}_i^{(e)} = \mathrm{KDF}(\mathrm{epoch_secret}, \mathrm{IK}_i^{\mathrm{pub}})$. *The sender chain advances symmetrically:* $\mathrm{MK}_{i,j} = \mathrm{HMAC}(\mathrm{CK}_{i,j}, \mathit{0x01})$ *and* $\mathrm{CK}_{i,j+1} = \mathrm{HMAC}(\mathrm{CK}_{i,j}, \mathit{0x02})$.

Each group message is encrypted once under the sender's chain key and distributed to all members, who can independently derive the same message key from the sender's chain.

5.4 Group Message Format

Listing 1: Group Message Structure

```go
type GroupMessage struct {
    // Group identifier
    GroupID   [32]byte
    // Sender's identity (public key hash)
    Sender    [32]byte
    // Group epoch number
    Epoch     uint64
    // Message counter in sender's chain
    Counter   uint64
    // Encrypted payload (AES-256-GCM)
    Payload   []byte
    // Signature over all fields
    // (Ed25519, for sender authentication)
    Signature [64]byte
}

type GroupState struct {
    ID        [32]byte
    Epoch     uint64
    Tree      *TreeKEM
    Members   map[[32]byte]*MemberState
    MyLeaf    uint32
    MyChain   *SenderChain
    Chains    map[[32]byte]*SenderChain
}

type SenderChain struct {
    ChainKey [32]byte
    Counter  uint64
    Skipped  map[uint64][32]byte
}
```

6 Forward Secrecy Analysis

6.1 Per-Message Forward Secrecy

Theorem 6.1 (Per-Message Forward Secrecy)**.** *PSP provides forward secrecy at the granularity of individual messages in pairwise sessions. Compromise of the current ratchet state at time t does not reveal message keys for messages sent before t.*

Proof. Let MK_j be the key for message j and CK_j the chain key at step j. By construction: $\mathrm{CK}_{j+1} = \mathrm{HMAC}(\mathrm{CK}_j, \mathtt{0x02})$ and $\mathrm{MK}_j = \mathrm{HMAC}(\mathrm{CK}_j, \mathtt{0x01})$. HMAC-SHA256 is a PRF under

the assumption that SHA-256 is a random oracle [9]. Given CK_{j+1}, computing CK_j requires inverting the PRF, which is infeasible. Therefore MK_j is unreachable from CK_{j+1}.

For DH ratchet steps, the root key RK_{i+1} depends on the DH output $\mathrm{DH}(\mathrm{DHs}_i, \mathrm{DHr}_i)$. After the ratchet step, DHs_i is deleted. Recovering RK_i from RK_{i+1} requires the deleted DH secret, which is infeasible under the CDH assumption on Curve25519. □

6.2 Group Forward Secrecy

Theorem 6.2 (Group Forward Secrecy)**.** *When member M_r is removed from a group, all subsequent group messages are confidential from M_r, provided the removing member's path update uses fresh key material.*

Proof. Upon removal, all nodes on the path from M_r's leaf to the root are blanked. The updating member generates fresh key pairs for all nodes on their own path, deriving a new root secret. The path secrets are encrypted for co-path nodes, none of which include M_r's leaf. Since M_r's leaf has been blanked and the path to the root has been re-keyed, M_r cannot derive the new epoch secret. □

7 Post-Compromise Security

Definition 7.1 (Post-Compromise Security)**.** *A protocol provides PCS if, after an adversary compromises a party's state at time t, subsequent messages (after sufficient healing interactions) are secure despite the compromise.*

Theorem 7.1 (PSP Post-Compromise Security)**.** *PSP achieves PCS in pairwise sessions after at most two DH ratchet steps following state compromise.*

Proof. Let the adversary compromise party A's state, learning DHs_A, RK, CKs, and CKr. After A sends a message, the adversary knows A's new DH public key. When B responds, B generates a fresh ephemeral DHs_B unknown to the adversary. The DH output $\mathrm{DH}(\mathrm{DHs}_A, \mathrm{DHs}_B)$ is known to the adversary (since they know DHs_A). However, when A sends the next message with a fresh DHs'_A (generated after the compromise), the DH output $\mathrm{DH}(\mathrm{DHs}'_A, \mathrm{DHs}_B)$ is unknown to the adversary. The root key derived from this DH output is computationally indistinguishable from random, restoring security. □

8 Deniability

8.1 Offline Deniability

PSP provides offline deniability: given a transcript, a third party cannot determine whether it was produced by the claimed participants or by a simulator.

Theorem 8.1 (Deniability)**.** *PSP is deniable in the sense that for any transcript T between parties A and B, there exists a PPT simulator $\mathcal{S}$ that produces transcripts computationally indistinguishable from T given only A's and B's public keys.*

Proof sketch. X3DH uses DH operations rather than digital signatures for key agreement. Any party who knows one side's private key can compute the same DH outputs. Message MACs (within AEAD) use symmetric keys derivable by either party. Therefore, either A or B can independently produce a valid-looking transcript. A simulator with access to either party's key can produce indistinguishable transcripts. □

8.2 Limitation: Group Deniability

Group messages include Ed25519 signatures for sender authentication (Section 5). This provides non-repudiation within the group, which is a deliberate design choice: group members need to know who sent a message. However, this makes group messages non-deniable. We mitigate this through:

1. Signatures use group-specific signing keys rotated each epoch.
2. Keys are deleted after epoch expiry.
3. After key deletion, the signature is unverifiable by any party not in the group during that epoch.

9 Integration with Pars Network

9.1 Identity Anchoring

PSP identity keys are anchored to the Pars DID system (PNP-008):

Listing 2: Identity Anchoring

```go
type PSPIdentity struct {
    DID         string    // pars:did:0x...
    IKPub       [32]byte  // Ed25519 public key
    KEMPub      []byte    // ML-KEM-768 public key
    DIDProof    []byte    // DID authentication proof
    Timestamp   uint64
    Signature   [64]byte  // Ed25519 over all fields
}

func (id *PSPIdentity) Verify(
    resolver DIDResolver,
) error {
    doc, err := resolver.Resolve(id.DID)
    if err != nil {
        return fmt.Errorf("DID resolve: %w", err)
    }
    // Verify IK matches DID document
    if !bytes.Equal(
        doc.AuthenticationKey, id.IKPub[:],
    ) {
        return fmt.Errorf("IK mismatch")
    }
    // Verify self-signature
    msg := encodeForSig(id)
    if !ed25519.Verify(
        id.IKPub[:], msg, id.Signature[:],
    ) {
        return fmt.Errorf("bad signature")
    }
    return nil
}
```

9.2 Session Directory

Prekey bundles are stored in a distributed session directory implemented as a DHT on the Pars mesh layer (PNP-002). Bundle integrity is ensured through signatures, and availability through

replication across $k = 20$ closest nodes.

9.3 Transport Layer

PSP messages are transported over the Pars mesh network. The session protocol is transport-agnostic; it produces ciphertext blobs that the mesh layer routes through the appropriate tier (internet overlay, local BLE mesh, or Tor/I2P bridge).

10 Performance Analysis

10.1 Computational Cost

Table 2: Operation Timing (iPhone 15 Pro, M3-class)

Operation	**Time**
X3DH session establishment (classical)	0.8 ms
X3DH session establishment (hybrid PQ)	2.1 ms
DH ratchet step	0.4 ms
Symmetric ratchet step	0.01 ms
AES-256-GCM encrypt (1 KB)	0.005 ms
ML-KEM-768 encapsulate	0.3 ms
ML-KEM-768 decapsulate	0.2 ms
Ed25519 sign	0.05 ms
Ed25519 verify	0.12 ms
TreeKEM update ($n = 1000$)	4.2 ms

10.2 Message Overhead

Table 3: Per-Message Byte Overhead

Component	**Bytes**
DH public key (Curve25519)	32
Previous chain length	4
Message counter	4
AEAD nonce	12
AEAD tag	16
Message type / version	4
Total (pairwise)	**72**
Group ID	32
Sender ID	32
Epoch	8
Counter	8
AEAD nonce + tag	28
Ed25519 signature	64
Total (group)	**172**

10.3 End-to-End Latency

Including network round-trip via the Pars mesh:

Table 4: End-to-End Latency Breakdown

Phase	**Time**
Prekey bundle retrieval (DHT lookup)	180 ms
X3DH computation (hybrid)	2.1 ms
Initial message encryption	0.01 ms
Mesh routing (3-hop, Tier 1)	120 ms
Total session establishment	**302 ms**
Subsequent message encrypt + route	120.4 ms

11 Formal Security Model

11.1 UC Framework

We define the ideal functionality $\mathcal{F}_{\text{PSP}}$ in the Universal Composability framework [1]:

Definition 11.1 (Ideal Functionality $\mathcal{F}_{\text{PSP}}$)**.** *$\mathcal{F}_{\text{PSP}}$ maintains a table of sessions. On input $(\textsc{Send}, \text{sid}, m)$ from party A, $\mathcal{F}_{\text{PSP}}$ delivers $(|m|, A)$ to the adversary and, if the adversary permits, delivers m to party B. The adversary learns $|m|$ (message length) and the identities of A and B, but not m. On compromise of party A, $\mathcal{F}_{\text{PSP}}$ reveals all future messages from A until a healing event occurs.*

Theorem 11.1 (UC Realisation)**.** *PSP UC-realises $\mathcal{F}_{\text{PSP}}$ in the random oracle model under the Gap-CDH assumption on Curve25519 and the ML-KEM IND-CCA2 assumption.*

The proof follows by construction of a simulator that translates between the ideal functionality and the real protocol, using the security of X3DH for session establishment and the Double Ratchet's forward-secrecy and PCS properties for ongoing communication. The full proof is deferred to the extended version.

12 Conclusion

The Pars Session Protocol provides a complete suite of end-to-end encrypted communication primitives for the Pars Network. Key properties include per-message forward secrecy, post-compromise security within two ratchet steps, hybrid classical/post-quantum key exchange, efficient group sessions via TreeKEM, and offline deniability for pairwise sessions. Performance analysis demonstrates that PSP is practical for mobile devices, with session establishment under 300 ms and message overhead of 72–172 bytes.

Future work includes integration with the Pars zero-knowledge identity system (PNP-006) for anonymous session establishment and formal verification of the group session protocol using ProVerif or Tamarin.

A PSP Message Wire Format

Listing 3: Binary Wire Format

```
PSP Pairwise Message (variable length):
  +--------+--------+-------+-------+
  | Version| Type   | DHPub | Prev  |
  | 1 byte | 1 byte |32 byte| 4 byte|
  +--------+--------+-------+-------+
  | Counter| Nonce  | Ciphertext    |
  | 4 byte |12 byte | variable      |
  +--------+--------+---------------+
  | AEAD Tag                        |
  | 16 bytes                        |
  +---------- ---------------------+

PSP Group Message (variable length):
  +--------+--------+--------+------+
  | Version| Type   | GroupID| Sender|
  | 1 byte | 1 byte |32 byte|32 byte|
  +--------+--------+--------+------+
  | Epoch  | Counter| Nonce  | CT   |
  | 8 byte | 8 byte |12 byte| var  |
  +--------+--------+--------+------+
  | AEAD Tag| Ed25519 Signature     |
  | 16 byte | 64 bytes              |
  +---------+----------------------+
```

B Key Derivation Functions

Listing 4: KDF Implementations

```go
func KDF_RK(
    rk [32]byte, dhOut [32]byte,
) (newRK, ck [32]byte) {
    prk := hkdf.Extract(sha256.New,
        dhOut[:], rk[:])
    r := hkdf.Expand(sha256.New,
        prk, []byte("PSP-RK"), 64)
    copy(newRK[:], r[:32])
    copy(ck[:], r[32:64])
    return
}

func KDF_CK(
    ck [32]byte,
) (newCK, mk [32]byte) {
    mk = hmacSHA256(ck[:], []byte{0x01})
    newCK = hmacSHA256(ck[:], []byte{0x02})
    return
}
```

```go

func hmacSHA256(
    key, data []byte,
) [32]byte {
    h := hmac.New(sha256.New, key)
    h.Write(data)
    var out [32]byte
    copy(out[:], h.Sum(nil))
    return out
}
```
